Quiz– 15

MCQs:

1. What is exception handling in Python?
 - A) A way to handle errors that occur during program execution
 - B) A way to prevent errors from occurring
 - C) A way to log information about errors
 - D) A way to stop the program when an error occurs

2. How do you handle exceptions in Python?
 - A) By using the `try` and `except` blocks
 - B) By using the `try` and `finally` blocks
 - C) By using the `except` block only
 - D) By using the `try`, `except`, and `else` blocks

3. What is the purpose of the `try` block in exception handling?
 - A) To catch and handle exceptions
 - B) To specify the code that may raise an exception
 - C) To execute code that should always run
 - D) To define the type of exception to catch

4. What is the purpose of the `except` block in exception handling?
 - A) To specify the code that may raise an exception
 - B) To catch and handle exceptions
 - C) To execute code that should always run
 - D) To define the type of exception to catch

5. What is the purpose of the `finally` block in exception handling?

- A) To catch and handle exceptions
- B) To specify the code that may raise an exception
- C) To execute code that should always run, whether or not an exception occurs
- D) To define the type of exception to catch

6. How do you raise an exception manually in Python?

- A) By using the `raise` keyword followed by an exception type
- B) By using the `throw` keyword followed by an exception type
- C) By using the `raise` keyword followed by an exception instance
- D) By using the `throw` keyword followed by an exception instance

7. Which keyword is used to define the type of exception to catch in a `except` block?

- A) `catch`
- B) `except`
- C) `handle`
- D) `trap`

8. What is the purpose of the `else` block in exception handling?

- A) To catch and handle exceptions
- B) To execute code that should always run
- C) To define the type of exception to catch
- D) To execute code if no exceptions occur

9. What is the output of the following code?

try:

```
num = int(input("Enter a number: "))
```

```
print("The square of the number is:", num**2)
except ValueError:
    print("Invalid input. Please enter a valid number.")
```

- A) The square of the number entered
- B) "Invalid input. Please enter a valid number."
- C) The input prompt is displayed again
- D) None of the above

10. What is the output of the following code?

```
try:
    raise ValueError("An error occurred")
except ValueError as e:
    print("Error:", e)
```

- A) "An error occurred"
- B) "Error: An error occurred"
- C) ValueError: An error occurred
- D) Error: ValueError: An error occurred
